BACKGROUND

1. Field

The present disclosure relates to an ice-making machine, and more particularly, to an analysis of an acoustic wave that is propagating through a body of water in the ice-making machine. The analysis recognizes when the body of water is frozen, so that the body of water can be harvested, as ice, from the ice-making machine. The analysis also diagnoses operations of devices in the ice-making machine.

2. Description of the Related Art

The approaches described in this section are approaches that could be pursued, but not necessarily approaches that have been previously conceived or pursued. Therefore, unless otherwise indicated, the approaches described in this section may not be prior art to the claims in this application and are not admitted to be prior art by inclusion in this section.

For efficient operation of an ice-making machine, it is desirable to remove the ice, also known as harvesting the ice, soon after the ice has fully formed. Such harvesting of the ice allows for a new body of water to be introduced so that a new body of ice can be formed, thus maximizing the usage of the ice-making machine.

One technique for recognizing the readiness of the ice for harvesting is to monitor a magnitude of a mechanical vibration that is propagating through a body of water as the body of water is being frozen. At a point in time when the magnitude exceeds a predetermined threshold, the body of water is assumed to be adequately frozen, and so, is harvested.

This existing technique uses only amplitude change above a set threshold to detect ice formation. This technique has a drawback in that it does not distinguish between various possible sources of mechanical vibrations, and so, cannot determine whether the change is due to a change in acoustics of the ice-making machine or spurious acoustics in an ambient noise environment. Consequently, the existing technique does not necessarily initiate harvesting at a most optimum time, and therefore, the ice-making machine may be operating at a less than optimum level of efficiency.

SUMMARY

There is provided a method that includes: (i) detecting an acoustic wave that is propagating through a body of water, as the body of water is being frozen on a structure, thus yielding a detected acoustic wave; (ii) extracting, from the detected acoustic wave, (a) a frequency component thereof, and (b) a magnitude of the frequency component; and (iii) removing the body of water from the structure when the magnitude exceeds a threshold value.

There is also provided a method that includes: (a) detecting an acoustic wave that is propagating through a body of water,

2

as the body of water is being frozen on a structure in an ice-making machine, thus yielding a detected acoustic wave; (b) analyzing the detected acoustic wave to yield a spectrum thereof; (c) determining whether the spectrum includes a spectral signature, thus yielding a determination, wherein the spectral signature is present when a device in the ice-making machine is operating; and (d) issuing an alert based on the determination.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a functional block diagram of a system implemented in an ice-making machine.

FIG. 2 is a functional block diagram of control board in the system of FIG. 1.

FIGS. 3A and 3B are, together, a flowchart of an ice-sensing process that is implemented on the control board of FIG. 2.

FIG. 4 is a flowchart of a system diagnostics process that is implemented on the control board of FIG. 2.

FIG. 5 is a block diagram of a system that executes the operations of the ice-sensing process of FIG. 2 and the system diagnostics process of FIG. 3.

FIG. 6 is a cross-section view of a probe on an evaporator.

FIG. 7 is a picture of a probe mounted to an evaporator.

FIG. 8 is a side view of an integrated sensor microphone.

A component or a feature that is common to more than one drawing is indicated with the same reference number in each of the drawings.

DESCRIPTION OF THE PREFERRED EMBODIMENT

FIG. 1 is a functional block diagram of a system, referred to herein as system **100**, implemented in an ice-making machine. System **100** performs various digital signal processing operations on an acoustic signal from an ice thickness sensor, using a fast Fourier transform (FFT) algorithm, for increasing reliability of ice detection and for providing enhanced system diagnostics on the ice-making machine.

System **100** includes an evaporator **102**, a compressor **104**, a water pump, i.e., pump **106**, a control board **130** and a solenoid **160**. Evaporator **102** includes a sensor **110**. Control board **130** includes a microphone **140**, a processing module **145** and a relay **150**. The term "module" is used herein to denote a functional operation that may be embodied either as a stand-alone component or as an integrated configuration of a plurality of sub-ordinate components.

System **100** runs through an ice-making cycle that includes a pre-chill stage, a freeze stage, a harvest stage and a purge stage.

Evaporator **102** is a structure for forming ice thereon. Pump **106** pumps and circulates water **115**, in a liquid state, so that water **115** flows over evaporator **102** and collects as a body of water, i.e., water **103** (in FIG. 1, represented with a perimeter having a dashed line), that is being frozen into a solid state, i.e., ice.

Evaporator **102** has a coil (not shown) through which is routed either of a cold gas or a hot gas. Compressor **104** facilitates the routing of the cold gas through the coil. When the cold gas is routed through the coil, water **103** freezes, thus forming as ice on evaporator **102**. In practice, water **115** cascades over evaporator **102**, and freezes gradually, so that water **103** forms into a block of ice. After water **103** forms as ice, the hot gas is routed through the coil, thus heating evaporator **102** and slightly melting the ice so that the ice, and more particularly water **103** in the form of ice, can be removed.

Evaporator **102** may also include a grid (not shown) for holding water **103** and forming water **103** in the shape of cubes, or any other desired shape.

Compressor **104**, during operation, emits a mechanical vibration **105**, and pump **106**, during operation, emits a mechanical vibration **107**. Each of mechanical vibration **105** and mechanical vibration **107** propagates through physical structures in system **100**, and through water **103**, as an acoustic wave **108**. Thus, acoustic wave **108** may include contributions from either or both of mechanical vibration **105** and mechanical vibration **107**.

Sensor **110**, e.g., a diaphragm having a dimple, is a detector that detects acoustic wave **108**, thus yielding a detected acoustic wave **117**. Sensor **110** may be situated, for example, on a surface of evaporator **102**, or at any location at which it can receive and detect acoustic wave **108**. An acoustic wave conduit **120**, e.g., a plastic tube, couples detected acoustic wave **117** from sensor **110** to microphone **140**. Microphone **140** converts detected acoustic wave **117** into an analog electrical signal **122**. Processing module **145** receives analog electrical signal **122**, converts it into a digital signal and analyzes it, thus effectively analyzing detected acoustic wave **117**.

Processing module **145**, based on its analysis of detected acoustic wave **117**, determines whether water **103** has formed into ice, and if yes, issues a signal **124** to remove water **103**, as ice, from evaporator **102**. More particularly, when processing module **145** has determined that water **103** has formed into ice, processing module **145** issues signal **124** to relay **150**, which in turn issues an actuation signal **155** that energizes solenoid **160**. Energizing solenoid **160** causes the routing of the hot gas through the coil of evaporator **102**, which causes water **103** to slightly melt and become free from evaporator **102**. The removal of the ice is also referred to as harvesting.

As noted above, acoustic wave **108** may include contributions from either or both of mechanical vibration **105** and mechanical vibration **107**. Accordingly, either of mechanical vibration **105** or mechanical vibration **107** could be the source of acoustic wave **108**, and as such, could be the source of detected acoustic wave **117** for the analysis performed by processing module **145**.

Each of mechanical vibration **105** and mechanical vibration **107** is unique, and as such, provides a unique spectral signature for each of compressor **104** and pump **106**. Processing module **145** analyzes detected acoustic wave **117** and draws some conclusions about the operations of compressor **104** and pump **106**. For example, processing module **145**, by way of communications with other components of system **100**, knows in which ice-making stage system **100** is operating, and also knows when compressor **104** should turn ON, and when compressor **104** should turn OFF. Accordingly, processing module **145**, based on its analysis of detected acoustic wave **117**, also determines whether compressor **104** turns ON or OFF at its appropriate times. If processing module **145** determines that compressor **104** is not operating properly, then processing module **145** issues an alert signal **165**. Alert signal **165** could be manifested, for example, as a fault indicator on a user interface (not shown in FIG. 1). Processing module **145** makes a similar determination for the operation of pump **106**, and alert signal **165** indicates the operating status of pump **106**.

FIG. 2 is a functional block diagram of control board **130**, and shows further details of processing module **145**. Processing module **145** includes a micro-controller **205**, and a digital signal processing module **210**.

As noted above, processing module **145** receives analog electrical signal **122** from microphone **140**. Micro-controller **205** includes analog circuitry (not shown) for amplifying and filtering analog electrical signal **122**, and an analog-to-digital converter (A/D) (not shown) that converts analog electrical signal **122** to a digital signal **208**. Thus, digital signal **208** is a digital representation of detected acoustic wave **117**. Digital signal processing module **210** receives digital signal **208** and processes it in accordance with methods designated herein as an ice-sensing process **215** and a system diagnostics process **220**.

In accordance with ice-sensing process **215**, digital signal processing module **210** analyzes digital signal **208** to determine whether water **103** has formed into ice, and if yes, issues signal **124** to relay **150**, which in turn issues actuation signal **155**. Ice-sensing process **215** is described in greater detail below, with reference to FIGS. 3A and 3B.

In accordance with system diagnostics process **220**, digital signal processing module **210** analyzes digital signal **208** to draw conclusions about the operations of compressor **104** and pump **106**, and if necessary, issues alert signal **165**. System diagnostics process **220** is described in greater detail below, with reference to FIG. 4.

In some situations, issues can occur in transmitting sound through tubes or connectors, or through a component making inadvertent contact with another component. Such an issue can trigger a false harvest signal. These issues can be avoided by embedding microphone **140** in a probe with sensor **110**, i.e., an integrated sensor microphone, that comes into contact with the ice (i.e., the body of water) or the evaporator, or is situated in close proximity, e.g., less than 0.5 inches, to the ice (i.e., the body of water) or the evaporator.

For example, in the context of the components shown in FIG. 1, microphone **140** and sensor **110** could be integrated together, thus resulting in an integrated sensor microphone. Accordingly, there will be no need for microphone **140** on control board **130**, and no need for acoustic wave conduit **120**. The integrated sensor microphone avoids issues with transmission of sound from sensor **110** to microphone **140**, and thus eliminates any chance of extraneous noise and vibration through acoustic wave conduit **120** to control board **130**, and improves the signal to noise ratio. Additionally, the entire integrated sensor microphone can be hermetically sealed to eliminate any chance of moisture entering sensor **110** or microphone **140**, and thus adversely impacting the performance of sensor **110** or microphone **140**.

An alternative to the integrated sensor microphone is an integrated sensor accelerometer that employs an accelerometer instead of microphone **140**. In the integrated sensor accelerometer, the accelerometer is used to measure the vibration transmitted through sensor **110**. The accelerometer converts the vibration energy into an electrical signal that is transmitted to control board **130**.

Either of the integrated sensor microphone or the integrated sensor accelerometer could be regarded as a sensing probe, and be situated on evaporator **102** in place of the stand-alone sensor **110**. The sensing probe produces an electrical signal, similar to analog electrical signal **122**, that is coupled into processing module **145**. An exemplary embodiment of such a sensing probe is described in greater detail below, with reference to FIGS. 6-8.

FIGS. 3A and 3B are, together, a flowchart of ice-sensing process **215**. As mentioned above, in accordance with ice-sensing process **215**, digital signal processing module **210** analyzes digital signal **208** to determine whether water **103** has formed into ice. Ice-sensing process **215** commences with step **310**.

5

In step 310, system 100 starts its freeze stage. Accordingly, water 115 cascades over evaporator 102, and water 103 is being frozen. Sensor 110 detects acoustic wave 108, thus yielding detected acoustic wave 117, and microphone 140 converts detected acoustic wave 117 into analog electrical signal 122. From step 310, ice-sensing process 215 progresses to step 320.

In step 320, the A/D in micro-controller 205 samples analog electrical signal 122 at some sampling frequency, e.g., 2.5 kilohertz (kHz), and converts analog electrical signal 122 into digital signal 208. Detected acoustic wave 117 is a time-domain signal, i.e., magnitude as a function of time. Digital signal 208 is a digital representation of detected acoustic wave 117, and as such, is also a time-domain signal.

The magnitude of detected acoustic wave 117 is dependent upon the magnitude of acoustic wave 108, which is in turn dependent upon magnitudes of mechanical vibration 105 and mechanical vibration 107, and thus dependent on physical factors such as the size of system 100. As such, the magnitude of detected acoustic wave 117, and quantities derived from the magnitude of detected acoustic wave 117 are dependent on the size of system 100.

From step 320, ice-sensing process 215 progresses to step 330.

In step 330, digital signal processing module 210 transforms digital signal 208 from a time-domain signal to a frequency-domain signal, i.e., magnitude as a function of frequency. More specifically, digital signal processing module 210 performs an FFT on digital signal 208. The FFT determines frequency components, and their respective magnitudes, of detected acoustic wave 117. For example, digital signal processing module 210 performs a 256 point FFT and saves the frequency components and their respective magnitudes to an FFT array 332. From step 330, ice-sensing process 215 progresses to step 340.

In step 340, digital signal processing module 210 extracts one or more frequency components of interest, and their respective magnitudes, from FFT array 332. For example, digital signal processing module 210 extracts a fundamental frequency component, a second harmonic of the fundamental frequency component, and a third harmonic of the fundamental frequency component, and magnitudes for each of the fundamental frequency, second harmonic and third harmonic. The fundamental frequency would be, for example, either of a fundamental frequency of mechanical vibration 105 or a fundamental frequency of mechanical vibration 107. From step 340, ice-sensing process 215 progresses to step 350.

The fundamental frequency of mechanical vibration 105 and the fundamental frequency of mechanical vibration 107 may be inherent properties of compressor 104 and pump 106, and therefore, known in advance. Otherwise, these fundamental frequencies could be obtained through observation, or during a learning mode of ice-sensing process 215. For example, to learn the fundamental frequency of mechanical vibration 105, digital signal processing module 210, by way of communications with other components of system 100, would (a) turn OFF compressor 104 and evaluate a first spectrum of detected acoustic wave 117, and then (b) turn ON compressor 104 and evaluate a second spectrum of detected acoustic wave 117. The fundamental frequency of mechanical vibration 105 would appear as a dominant frequency component in the second spectrum, but not in the first spectrum. Alternatively, rather than digital signal processing module 210 controlling the ON/OFF states of compressor 104, system 100 may proceed in a regular mode of operation and notify digital signal processing module 210 when compressor 104 is ON or OFF.

6

In the next couple of steps, in the early part of the freeze stage, for example, within the first two minutes, before water 103 has formed as block of ice, digital signal processing module 210 obtains ambient acoustic levels of the frequencies of interest. Although in the present example, the early part of the freeze stage is regarded as a period of two minutes, other time durations are possible, e.g., six minutes.

In step 350, digital signal processing module 210 considers whether the freeze stage is in its early part. If the freeze stage is in its early part, then ice-sensing process 215 progresses from step 350 to step 354. If the freeze stage is not in its early part, then ice-sensing process 215 branches from step 350 to step 360.

In step 354, which is performed when the freeze stage is in its early part, digital signal processing module 210 stores the frequency components of interest, and their magnitudes, in a threshold array 352. From step 354, ice-sensing process 215 loops back to step 320.

By looping back to step 320, and progressing through steps 330, 340, 350 and 354, ambient acoustic levels of the frequencies of interest are repeatedly captured and stored in threshold array 352.

In step 360, which is performed when the freeze stage is not in its early part, for each of the frequencies of interest having magnitudes in threshold array 352, digital signal processing module 210 calculates an average magnitude, and stores the average magnitude in an average magnitude array 361. To the average magnitude, digital signal processing module 210 adds a margin, e.g. 3 decibels (dB), thus yielding a resultant threshold, and stores the resultant threshold into an ice detection threshold array 362. Ice detection threshold array 362 will thus hold a resultant threshold for each of the frequencies of interest. From step 360, ice-sensing process 215 progresses to step 365.

In step 365, digital signal processing module 210 tests for failures of sensor 110, microphone 140 (or the accelerometer being used in place of microphone 140) or, in the case of these components being integrated together, the sensing probe, collectively referred to as ice probe faults. Accordingly, for each of the frequency components of interest, digital signal processing module 210 calculates a standard deviation of the average magnitudes in average magnitude array 361. For each of the frequency components of interest, the standard deviation is compared to a probe fault lower threshold 363, and a probe fault upper threshold 364. If for any of the frequency components of interest, the standard deviation is less than probe fault lower threshold 363 or greater than probe fault upper threshold 364, there is assumed to be a fault of one or more of sensor 110, microphone 140 (or the accelerometer being used in place of microphone 140) or, in the case of these components being integrated together, the sensing probe. Although step 365 is being described as part of ice sensing process 215, it could be performed as part of system diagnostics 220.

As mentioned above, the magnitude of detected acoustic wave 117, and quantities derived from the magnitude of detected acoustic wave 117 are dependent on the size of system 100. Accordingly, appropriate values for probe fault lower threshold 363 and probe fault upper threshold 364 would be determined through experimentation.

From step 365, if the test passes, i.e., no fault is detected, then ice-sensing process 215 progresses to step 370. If the test fails, i.e., a fault is detected, then ice-sensing process 215 progresses to step 366.

In step 366, digital signal processing module 210 issues an ice probe fault alert, for example, by way of alert 165.

Although step 366 is being described as part of ice sensing process 215, it could be performed as part of system diagnostics 220.

In step 370, as water 103 continues to freeze, digital signal processing module 210 captures and processes real-time samples of detected acoustic wave 117. More specifically, digital signal processing module 210 extracts, from detected acoustic wave 117, frequency components of interest, and their respective magnitudes. For a better signal-to-noise ratio (SNR), and therefore better data integrity, average real-time magnitudes are considered over a period of time, e.g., mean of five FFT magnitude values obtained over a one-second interval of time. From step 370, ice-sensing process 215 progresses to step 380.

In step 380, digital signal processing module 210 compares the magnitudes of the real-time frequency components of interest to their corresponding magnitudes in ice detection threshold array 362. This comparison is being made because, when water 103 is adequately formed as a block of ice, the real-time magnitudes of the frequencies of interest will be significantly greater than they were before the ice was formed.

In step 380, if none of the real-time magnitudes is greater than its corresponding magnitude in ice detection threshold array 362, then digital signal processing module 210 concludes that water 103 is not yet sufficiently frozen, and digital signal processing module 210 loops back to step 370.

In step 380, if, for any of the frequency components of interests, the real-time magnitude is greater than its corresponding magnitude in ice detection threshold array 362, then digital signal processing module 210 concludes that water 103 is sufficiently frozen, and digital signal processing module 210 progresses to step 390.

Referring still to step 380, although the progression to step 390 is described as occurring in a case where, for any of the frequency components of interests, the real-time magnitude is greater than its corresponding magnitude in ice detection threshold array 362, the test can be based on some other minimum number of frequency components of interest having real-time magnitudes greater than their corresponding magnitudes in ice detection threshold array 362. For example, the test may require that at least two out of three frequency components of interest have real-time magnitudes greater than their corresponding magnitudes in ice detection threshold array 362.

In step 390, digital signal processing module 210 issues signal 124 to relay 150, which in turn issues actuation signal 155 to energize solenoid 160. Energizing solenoid 160 results in the harvesting, i.e., removing, of water 103, in the form of ice, from evaporator 102.

FIG. 4 is a flowchart of system diagnostics process 220. As mentioned above, in accordance with system diagnostics process 220, digital signal processing module 210 analyzes digital signal 208 to draw conclusions about the operations of compressor 104 and pump 106, and if necessary, issues alert signal 165. In brief, digital signal processing module 210 evaluates acoustic signatures of devices within system 100 to determine whether or not the devices are energizing at appropriate times. Below, system diagnostics process 220 is described with regard to operations of compressor 104 and pump 106. However, system diagnostics process 220 can be employed to evaluate operations of any device in system 100 that generates a mechanical vibration (e.g., a dump valve, a harvest solenoid, and a water inlet valve). System diagnostics process 220 commences with step 410.

In step 410, system diagnostics process 220 commences operation. From step 410, system diagnostics process 220 progresses to step 420.

In step 420, digital signal processing module 210 operates in a learning mode in which digital signal processing module 210 analyzes and records mechanical vibrations produced by compressor 104 and pump 106. For example, by way of communications with other components of system 100, digital signal processing module 210 energizes, or is notified of the energization of, compressor 104. Compressor 104 generates mechanical vibration 105, which is manifested in acoustic wave 108, and detected by sensor 110, to produce detected acoustic wave 117. Digital signal processing module 210 analyzes detected acoustic wave 117 to obtain a spectral signature, i.e., frequency components and magnitudes, of compressor 104. Digital signal processing module 210, in a similar manner, obtains a spectral signature of pump 106. Digital signal processing module 210 stores the spectral signatures for each of compressor 104 and pump 106 in a spectral signature array 425. From step 420, system diagnostics process 220 progresses to step 430.

In step 430, as system 100 is running through its normal ice-making cycle (i.e., pre-chill, freeze, harvest and purge), digital signal processing module 210 performs FFTs and observes acoustic data. More specifically, digital signal processing module 210 analyzes detected acoustic wave 117 to yield a spectrum thereof. Digital signal processing module 210 stores the spectrum in a spectrum array 432. From step 430, system diagnostics process 220 progresses to step 435.

In step 435, digital signal processing module 210 considers whether either of compressor 104 or pump 106 should be energized in the present stage of the ice-making cycle. That is, digital signal processing module 210, by way of communications with other components of system 100, knows whether either of compressor 104 or pump 106 should be energized. If either of compressor 104 or pump 106 should not be energized, then system diagnostics process 220 loops back to step 430. If either of compressor 104 or pump 106 should be energized, then system diagnostics process 220 progresses to step 440.

In step 440, digital signal processing module 210 determines whether the spectrum from step 430 includes a spectral signature of the device, i.e., compressor 104 or pump 106, that should be energized. For example, assume that compressor 104 should be energized. Accordingly, digital signal processing module 210 determines whether spectrum array 432 includes the spectral signature of compressor 104 that is stored in spectral signature array 425. From step 440, system diagnostics process 220 progresses to step 450.

In step 450, if spectrum array 432 includes the spectral signature of the device being considered, e.g., compressor 104, then digital signal processing module 210 concludes that system 100 is operating properly, and accordingly system diagnostics process 220 loops back to step 430. If spectrum array 432 does not include the spectral signature of the device being considered, then digital signal processing module 210 concludes that system 100 is not operating properly, and accordingly system diagnostics process 220 progresses to step 460.

Referring still to step 450, recall that spectral signature array 425 contains a spectral signature for each of compressor 104 and pump 106. Accordingly, digital signal processing module 210 can therefore determine whether detected acoustic signal 117 includes either or both of mechanical vibration 105 and mechanical vibration 107. This also enables system diagnostics process 220 to distinguish between spectral contributions from compressor 104 and pump 106, and determine

whether either or both of compressor **104** and pump **106** is ON, and therefore diagnose operations of either or both of compressor **104** and pump **106**. Moreover, digital signal processing module **210** can make these determinations even in a case where detected acoustic signal **117** includes noise or spectral contributions from other devices in system **100**.

In step **460**, digital signal processing module **210** issues alert signal **165**.

Digital signal processing module **210** is described above as issuing alert signal **165** for a case where a device that is being considered is expected to be ON, but spectrum array **432** does not include the spectral signature of the device being considered. However, system diagnostics process **220** could be configured so that digital signal processing module **210** issues alert signal **165** in a case where a device is expected to be OFF, and so, the spectrum should not include the spectral signature of the device, but instead spectrum array **432** does include the spectral signature of the device. This situation could occur, for example, in a case where either system **100** fails to turn OFF the device, or the device is stuck in its ON state.

In review, system **100** includes a detector, i.e., sensor **110**, and a processor, i.e., processing module **145**. Sensor **110** detects acoustic wave **108**, which is propagating through a body of water, i.e., water **103**, as water **103** is being frozen on a structure, i.e., evaporator **102**, in an ice-making machine, thus yielding detected acoustic wave **117**.

Processing module **145**: extracts, from detected acoustic wave **117**, (a) a frequency component thereof, and (b) a magnitude of the frequency component; and issues a signal, i.e., signal **124**, to remove water **103** from evaporator **102** when the magnitude exceeds a threshold value.

Processing module **145** also: analyzes detected acoustic wave **117** to yield a spectrum thereof; determines whether the spectrum includes a spectral signature, thus yielding a determination, wherein the spectral signature is present when a device, e.g., compressor **104**, in the ice-making machine is operating; and issues an alert, i.e., alert signal **165**, based on the determination.

Detected acoustic wave **117** is a time-domain signal. Processing module **145**, to extract the frequency component and the magnitude: transforms the time-domain signal to a frequency-domain signal; and obtains the frequency component, and the magnitude, from the frequency-domain signal.

Also in system **100**, the threshold value against which the magnitude is compared may be regarded as a first threshold value, and accordingly, processing module **145**: also extracts, from detected acoustic wave **117**, (a) a harmonic of the frequency component, and (b) a magnitude of the harmonic; and issues signal **124** to relay **150** when both of (i) the magnitude exceeds the first threshold value, and (ii) the magnitude of the harmonic exceeds a second threshold value.

System **100** is described above with processing module **145** being implemented on control board **130**. As such, processing module **145**, or any of its components, and in particular digital signal processing module **210**, may be implemented in hardware (e.g., electronic circuitry) or firmware, or a combination thereof. Moreover, digital signal processing module **210** can be implemented in software, and run on a computer that is in communication with other components in system **100**.

FIG. **5** is a block diagram of a computer-implemented embodiment, hereinafter referred to as system **500**, of digital signal processing module **210**. System **500** includes a computer **505** that in turn includes a processor **515** and a memory **520**. System **500** is in communication with other components in system **100**.

Processor **515** is an electronic device configured of logic circuitry that responds to and executes instructions.

Memory **520** is a computer-readable medium encoded with a computer program. In this regard, memory **520** stores data and instructions that are readable and executable by processor **515** for controlling the operation of processor **515**. Memory **520** may be implemented in a random access memory (RAM), a hard drive, a read only memory (ROM), flash memory, or a combination thereof. One of the components of memory **520** is a program module **525**.

Program module **525** contains instructions for controlling processor **515** to execute the methods described herein. That is, instructions from program module **525**, when read by processor **515**, cause processor **515** to perform operations of ice-sensing process **215**, and system diagnostics process **220**.

Although program module **525** is described herein as being installed in memory **520**, and therefore being implemented in software, it could be implemented in any of hardware (e.g., electronic circuitry), firmware, software, or a combination thereof.

Processor **515** outputs a result of an execution of the methods described herein, for example, a fault indicator based on the issuance of alert signal **165**. Alternatively, processor **515** could direct the output to a remote device (not shown) via a network (not shown).

While program module **525** is indicated as being already loaded into memory **520**, it may be configured on a storage medium **535** for subsequent loading into memory **520**. Storage medium **535** is also a computer-readable medium that stores program module **525** thereon. Examples of storage medium **535** include a floppy disk, a compact disk, a magnetic tape, a read only memory, an optical storage media, universal serial bus (USB) flash drive, a digital versatile disc, or a zip drive. Alternatively, storage medium **535** can be a random access memory, or other type of electronic storage, located on a remote storage system and coupled to computer **505** via a network (not shown).

As mentioned above, microphone **140** and sensor **110** could be integrated together, thus resulting in an integrated sensor microphone, and an alternative to the integrated sensor microphone is an integrated sensor accelerometer that employs an accelerometer instead of microphone **140**. Either of integrated sensor microphone or the integrated sensor accelerometer could be regarded as a sensing probe.

FIG. **6** is a cross-section view of a sensing probe **605** on evaporator **102**. Sensing probe **605** includes a dimple **610** that is implemented as a part of sensor **110** and that contacts water **103** on evaporator **102**.

FIG. **7** is a picture of sensing probe **605** on evaporator **102**.

FIG. **8** is a cross-section view of sensing probe **605** configured as an integrated sensor microphone having microphone **140** embedded into a top opening.

The techniques described herein are exemplary, and should not be construed as implying any particular limitation on the present disclosure. It should be understood that various alternatives, combinations and modifications could be devised by those skilled in the art. For example, system **100** may include a plurality of sensors **110** for detecting acoustic wave **108** at various locations on water **103**, and steps associated with the processes described herein can be performed in any order, e.g., order of steps **435** and **430** can be reversed, unless otherwise specified or dictated by the steps themselves. Also, although acoustic wave **108** is described herein as resulting from mechanical vibrations of either compressor **105** or pump **107**, system **100** could include a special-purpose device that generates a particular vibration for analysis by processing module **145**. The present disclosure is intended to

11

embrace all such alternatives, modifications and variances that fall within the scope of the appended claims.

The terms “comprises” or “comprising” are to be interpreted as specifying the presence of the stated features, integers, steps or components, but not precluding the presence of one or more other features, integers, steps or components or groups thereof.

What is claimed is:

1. A method comprising:

detecting an acoustic wave that is propagating through a body of water, as said body of water is being frozen on a structure, thus yielding a detected acoustic wave;

extracting, from said detected acoustic wave, (a) a frequency component thereof, (b) a magnitude of said frequency component, (c) a harmonic of said frequency component, and (d) a magnitude of said harmonic; and removing said body of water from said structure when both of (i) said magnitude of said frequency component exceeds a first threshold value, and (ii) said magnitude of said harmonic exceeds a second threshold value.

2. The method of claim 1,

wherein said detected acoustic wave is a time-domain signal, and

wherein said extracting comprises:

transforming said time-domain signal to a frequency-domain signal; and

obtaining said frequency component, said magnitude of said frequency component, said harmonic, and said magnitude of said harmonic, from said frequency-domain signal.

3. A system comprising:

a detector that detects an acoustic wave that is propagating through a body of water, as said body of water is being frozen on a structure, thus yielding a detected acoustic wave; and

a processor that:

extracts, from said detected acoustic wave, (a) a frequency component thereof, (b) a magnitude of said frequency component, (c) a harmonic of said frequency component, and (d) a magnitude of said harmonic; and

issues a signal to remove said body of water from said structure when both of (i) said magnitude of said frequency component exceeds a first threshold value, and (ii) said magnitude of said harmonic exceeds a second threshold value.

12

4. The system of claim 3,

wherein said detected acoustic wave is a time-domain signal, and

wherein said processor, to extract said frequency component and said magnitude:

transforms said time-domain signal to a frequency-domain signal; and

obtains said frequency component, said magnitude of said frequency component, said harmonic, and said magnitude of said harmonic, from said frequency-domain signal.

5. The system of claim 3, wherein said detector comprises a microphone in a probe that is situated less than 0.5 inches from said structure.

6. The system of claim 3, wherein said detector comprises a microphone in a probe that is in contact with said structure.

7. The system of claim 3, wherein said detector comprises a microphone in a probe that is situated less than 0.5 inches from said body of water.

8. The system of claim 3, wherein said detector comprises a microphone in a probe that is in contact with said body of water.

9. A non-transitory computer-readable storage medium comprising instructions that are readable by a processor, and that when read by said processor cause said processor to:

extract, from a detected acoustic wave, (a) a frequency component thereof, (b) a magnitude of said frequency component, wherein said detected acoustic wave represents an acoustic wave that is propagating through a body of water, as said body of water is being frozen on a structure, (c) a harmonic of said frequency component, and (d) a magnitude of said harmonic; and

issue a signal to remove said body of water from said structure when both of (i) said magnitude exceeds a threshold value, and (ii) said magnitude of said harmonic exceeds a second threshold value.

10. The non-transitory computer-readable storage medium of claim 9, wherein said detected acoustic wave is a time-domain signal, and

wherein said processor, to extract said frequency component and said magnitude:

transforms said time-domain signal to a frequency-domain signal; and

obtains said frequency component, said magnitude of said frequency component, said harmonic, and said magnitude of said harmonic, from said frequency-domain signal.
